A public teaching signal

Close minus open | original project note | version 1

Formula and source meaning

Original project teaching note. No external paper text or real market observations. This is a traceable software exercise, not an investment strategy.

Formula: score = close - open.

Fields: open is the opening price for session t; close is the closing price for the same asset and session t. Both prices use the same arbitrary synthetic unit. The score is available only after session t closes. No trailing window is used.

Mathematical direction: a higher score means a larger close-minus-open price displacement for that session. A negative score means close is below open. This statement does not assert a relationship with any future return.

Scientific unknown: no economic mechanism or predictive validity is asserted. Keep the economic mechanism unresolved. A successful calculation is not a human review, causal finding, or investment-performance result.

The following identifier belongs only to this original project teaching note; it is not an external paper or a published alpha label.

Alpha#9001: (close - open)

A public teaching signal

Close minus open | original project note | version 1

Explicit engineering protocol

Input: 6 invented assets on 48 synthetic weekday sessions. The CSV contains a complete daily OHLCV grid, with quarter-unit prices and invented volume. One validation session has the same displacement for every asset to exercise the constant-signal skip rule. These are teaching fixtures, not an exchange calendar.

Engineering timing: form the signal after session t closes, enter at session t+1 open, and exit at session t+2 open. Signal, entry and exit must all fall inside validation. The final two validation signal days are purged. Test rows remain reserved; the calculation uses only the prefix through validation end.

Engineering weights: average cross-sectional ranks of score, centered by their mean and divided by the sum of absolute centered ranks. Skip a constant signal cross-section. Gross exposure is one and net exposure is zero on evaluated days. Costs, slippage, borrow, liquidity, capacity and fills are not modeled.

Reported quantities: validation-only rank IC, gross return, coverage and exact day counts. They test software arithmetic and alignment on invented data only. Human review and research validity remain pending.

Demo transport: responses are hand-authored fixtures passed through the normal proposal parser and validator. No model account, paid model, or network model request is involved. Literal citation checks do not establish semantic fidelity.
